Monitor Calibration **Etobicoke Camera Club** *Brian Quan, Equipment Chair, 2019 Nov*

Why calibrate your monitor?

- To ensure your images get a fair score during competitions
- To match your monitor's colours, brightness and other settings to a set standard ("calibrated")
- The ECC projector has been calibrated for each season

Can't I manually adjust my monitor?

- Sure, but there's an infinite number of settings for brightness, contrast, colour, etc.
- There's no guarantee that you'll match what will be shown on the ECC projector

What do I need to do?

- Buy a "Calibrator"
- Use it to calibrate your monitor(s)
- Repeat on a regular basis
- As monitors age, they need to be re-calibrated

What is a "Calibrator"?

- A hardware/software tool
- It measures how your monitor displays colours
- It builds a custom profile to correct your monitor

What about the ECC projector?

- At the start of each season, we calibrate the projector and backup projector with both notebook computers
- ECC has used
 Datacolor calibrators for over 10 years

What standard do we use?

- sRGB: standard default colorspace for the Internet for 8-bit colour (as used by JPEG files)
- Defined by International Color Consortium (ICC): IEC 61966-2-1: 1999

How does Calibration work?

- The calibrator measures the screen output for a set of standard test slides
- Then, the brightness of the monitor is adjusted to match a standard level

How does Calibration work?

- The results are stored in an ICC profile
- The ICC profile is automatically loaded into the video card each time the computer is started

How does Calibration work?

- Then, all images shown on that monitor by the computer are displayed in the calibrated colorspace
- Differences are evident in people, skies, plants and brightness levels

What else is needed?

- Learning to adjust white and black levels in images
- Without adjustment, whites may be featureless: 'burned out'; blacks may be also be featureless
- Adjust black output from "0" to "10-15"; white output from "255" to "240-245"
- Nothing is pure white (255) or black (0) in digital images

A. Shadows B. Midtones C. Highlights D. Output Level sliders

For more information...

 Search for "adjusting levels in Photoshop" or "...Lightroom", or "...Photoshop Elements", or whatever your image editing software: in the manual, your software publisher's support section, <u>DuckDuckGo.com</u> or other search engine

What else is needed?

- Review your JPEGs before submitting them to ECC in "Ifranview" (Windows) or "XnViewMP" (Mac or Windows)
- Both display images in only the ICC sRGB colorspace

Unless you really know for sure, Photoshop, Lightroom, and others may use a different colorspace (e.g. AdobeRGB): which will cause "*I didn't submit that*" on the ECC projector

It's a last opportunity to correct your image:
 -change embedded colorspace to sRGB
 -lower/raise white levels and/or brightness

For the software (free).

- "Ifranview": <u>https://ifranview.com</u>
- "XnViewMP": <u>https://xnviewmp.com</u>

How much is a Calibrator?

- Prices start around CDN\$230 and up
- Support your local camera stores
- Note: avoid Calibrators for "Pantone": which do not support ICC sRGB
- Note: newer models may be less expensive than older

Remember...

- Like a lens, camera body or monitor, a calibrator is a tool to improve your images, and an investment in your photography
- Learning white/black level adjustments and checking the JPEG version in an sRGB viewer gives you more control over your submitted images
